

Visitation of a mechanical reclamation unit for an inorganic binder system in Villingen-Schwenningen, on May 25-2012

Joint Project between
Technofond Gießereihilfsmittel GmbH,
Domnick Verfahrens- und Anlagentechnik and
AGVS Aluminium Werke GmbH Villingen

Process description of the mechanical reclamation unit for inorganic sand systems at AGVS Aluminium Werke GmbH Villingen

After the pouring process the used foundry sand is crushed in a vibratory sand lump crusher (3) and is set in it's originally shape.

In a buffer device (5) the used foundry sand is stored and is transferred batch-wise into the cleaning unit (6).

This cleaning unit consists of two agitators with several transversal agitation kits. The agitation kits are fitted on a shaft in various heights.

The agitators are moving against each other.

Below the cleaning unit (6) is a nozzle floor with an air box. This is used to move the sand constantly.

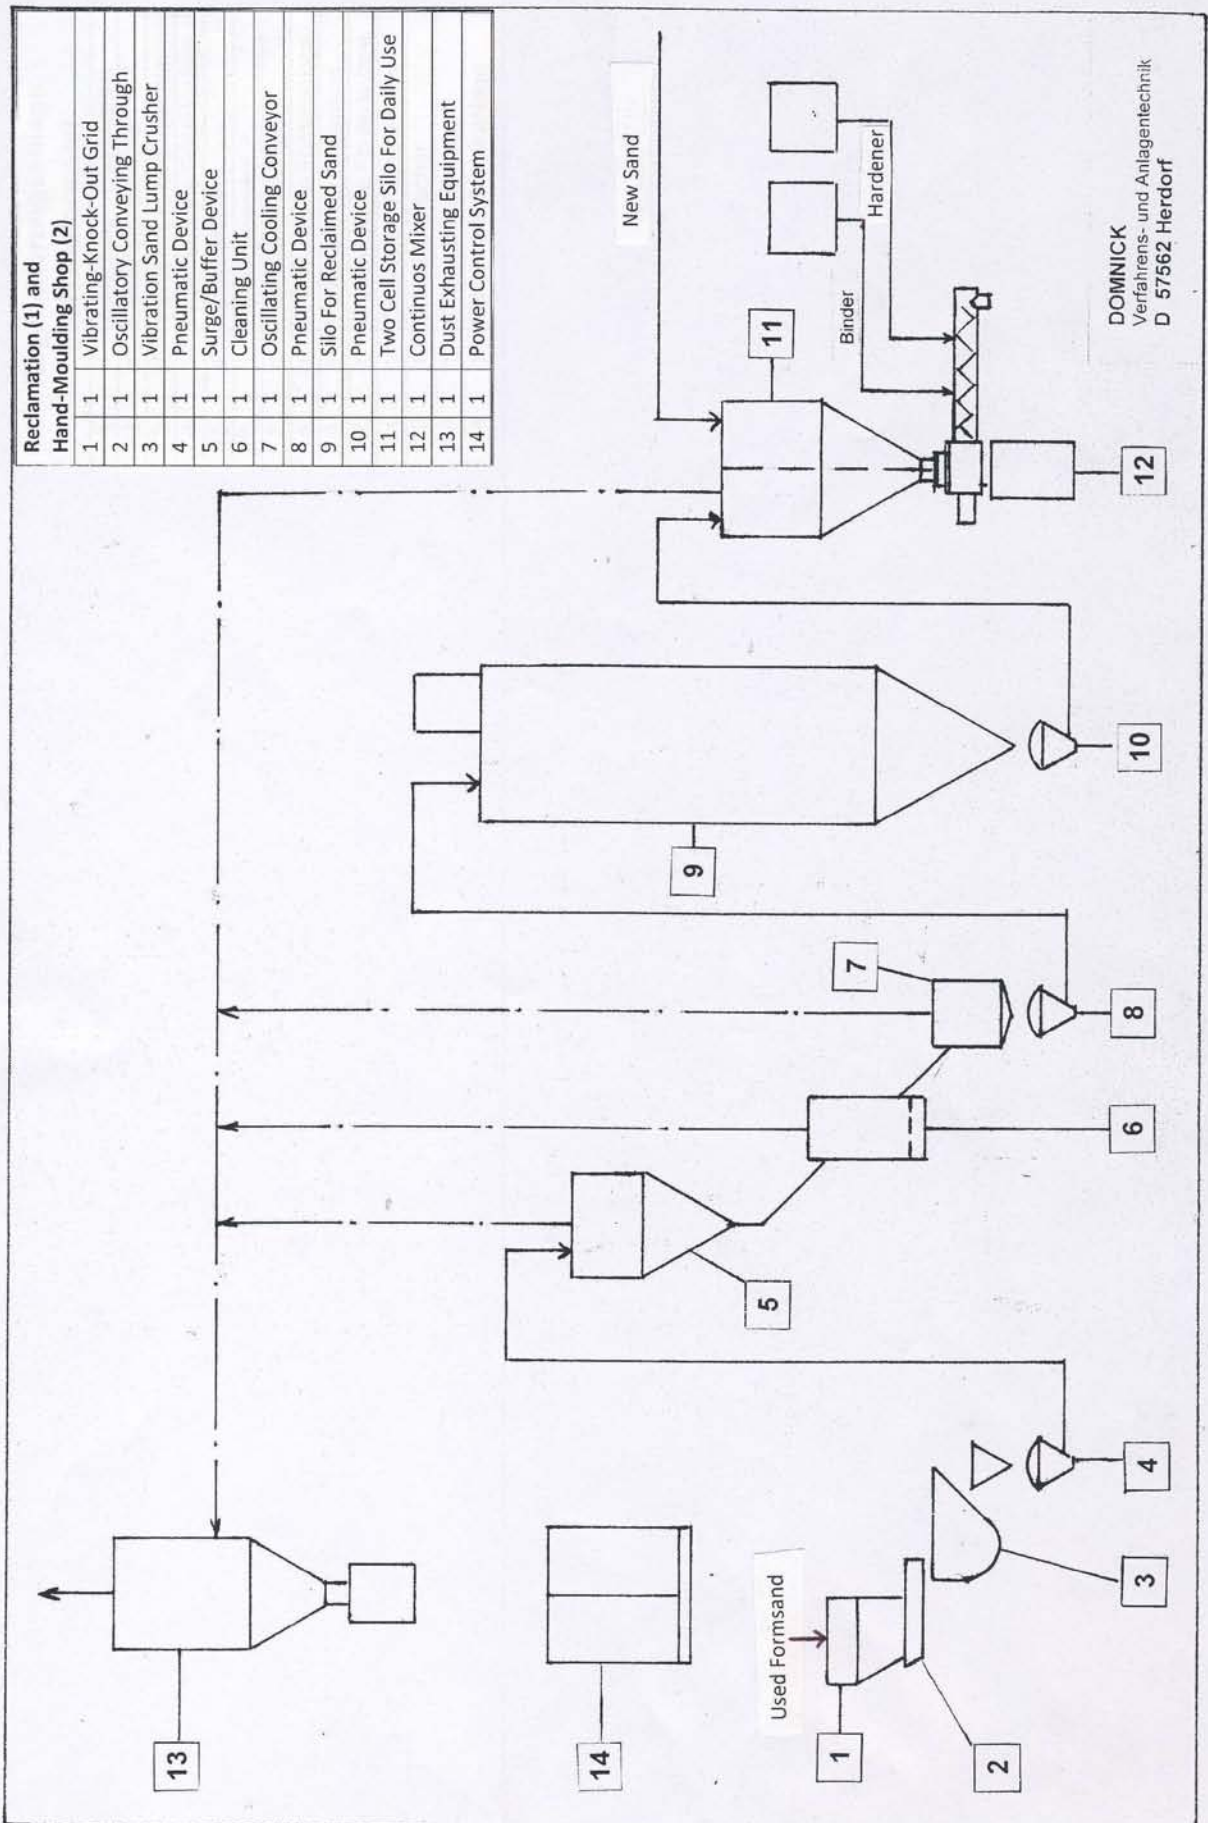

In the oscillating cooling conveyor (7) the sand is cooled to appropriate temperatures after the grinding process. The sand is removed from dust and conveyed to a hopper (9).

This process is running discontinuously.

During this mechanical cleaning process a significant share of the binder is removed from the sand grain.

The recycling of the sand for subsequent moulding requires that humidity and binder residues are removed, or existing only in a special condition, that the subsequent moulding process is not influenced in a negative way. This can be assured through the pilot unit at AGVS.

Note: The numbers shown are related to the position in the flow chart, next page.

Diagrams

List of Figures for Diagrams related to sand properties:

- Fig. 1 Average Grain Distribution related to Nos. of recycling passes
- Fig. 2 Bending strength of different sand mixtures prepared with Geopol[®]515 and Hardener SA73-T
- Fig. 3 Pressure strength measured with “PFP” from DISA
- Fig. 4 Bigger scale of the relevant area from Fig.3

Granulometric Analyse

Fig1: Grain Distribution related to different Nos. of passes through reclamation.

For H33 new sand the actual Product information Value for average grain size is shown (0,27 mm) and the value measured after the continuous mixer. There are only negligible deviations of the values achieved by reclaimed sand. Started autumn 2010 until present the average grain size was always near 0,29 mm.

In the surge device (5) before grinding the average grain size is up to 0,04 mm higher.

The total Sand and dust loss in 2011 was app. 7 %, always keeping in mind, that during this time scale many trials with test parameters for the reclamation unit were carried out.

Strength and Reactivity

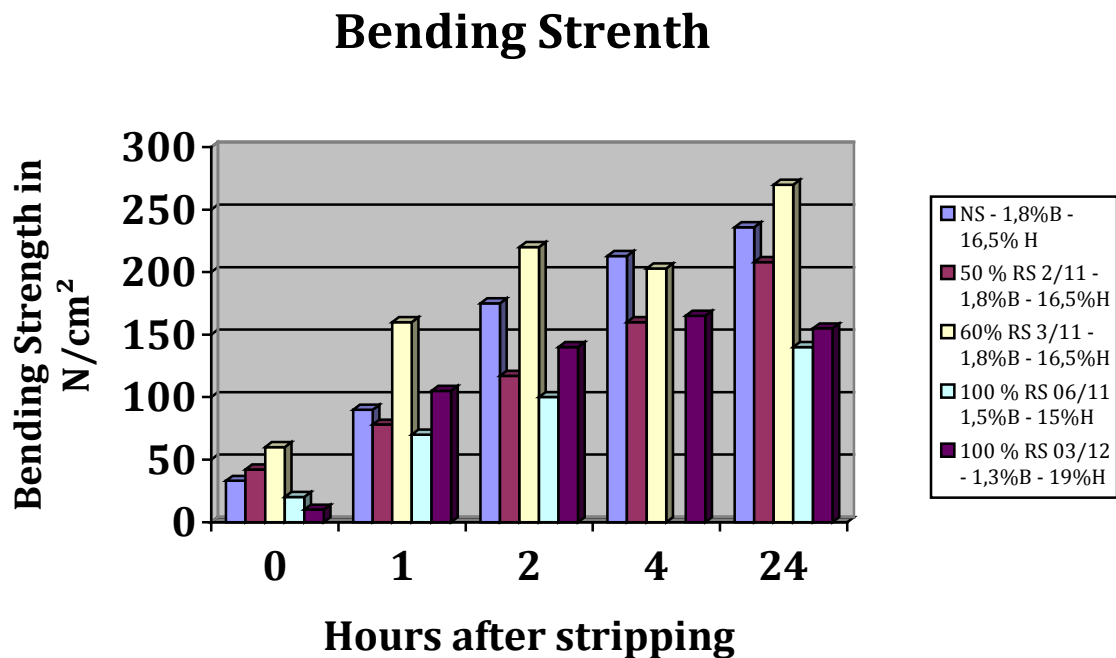

Fig.2: Bending Strength of various sand mixtures with Hardener SA73-T and Binder Geopol® 515.

The binder and hardener addition was reduced significantly during production.

All values shown were made with a GF Bend Test Piece.

Minimum of three measures per value shown were done.

The actual weight of the test piece was measured and was compared to average weight of all values. A maximum deviation of 3 % was allowed.

Mixer was a 6,0 t continuous mixer from Wöhr. Stripping Time was 1 hour for all test-samples.

Legend: NS-New Sand, RS-reclaimed sand, B-Binder, H-Hardener, 2/11 - month and year of test.

Pressure Strength

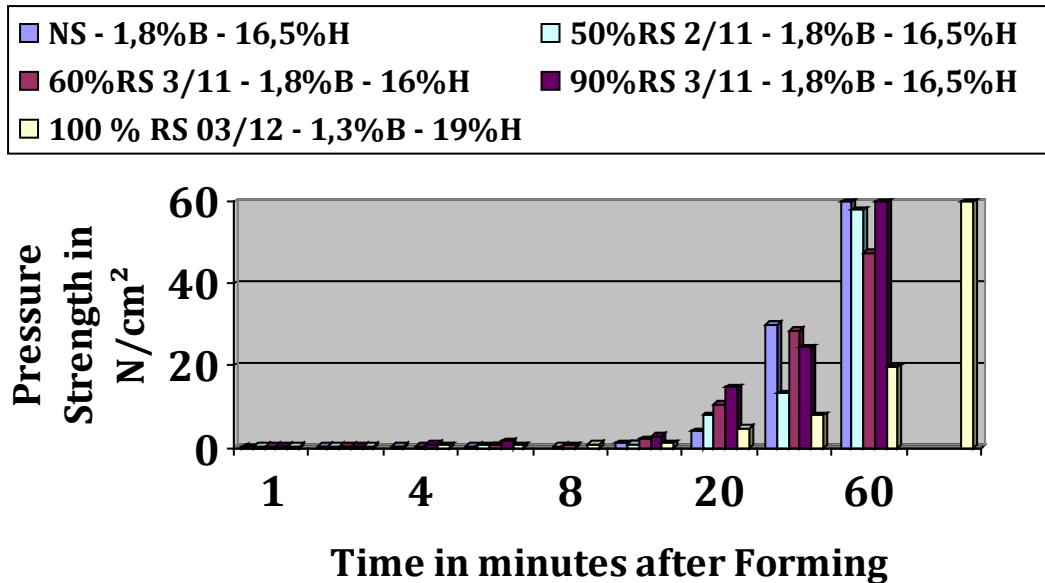

Fig.3: Pressure Strength tested with the “PFP” from DISA

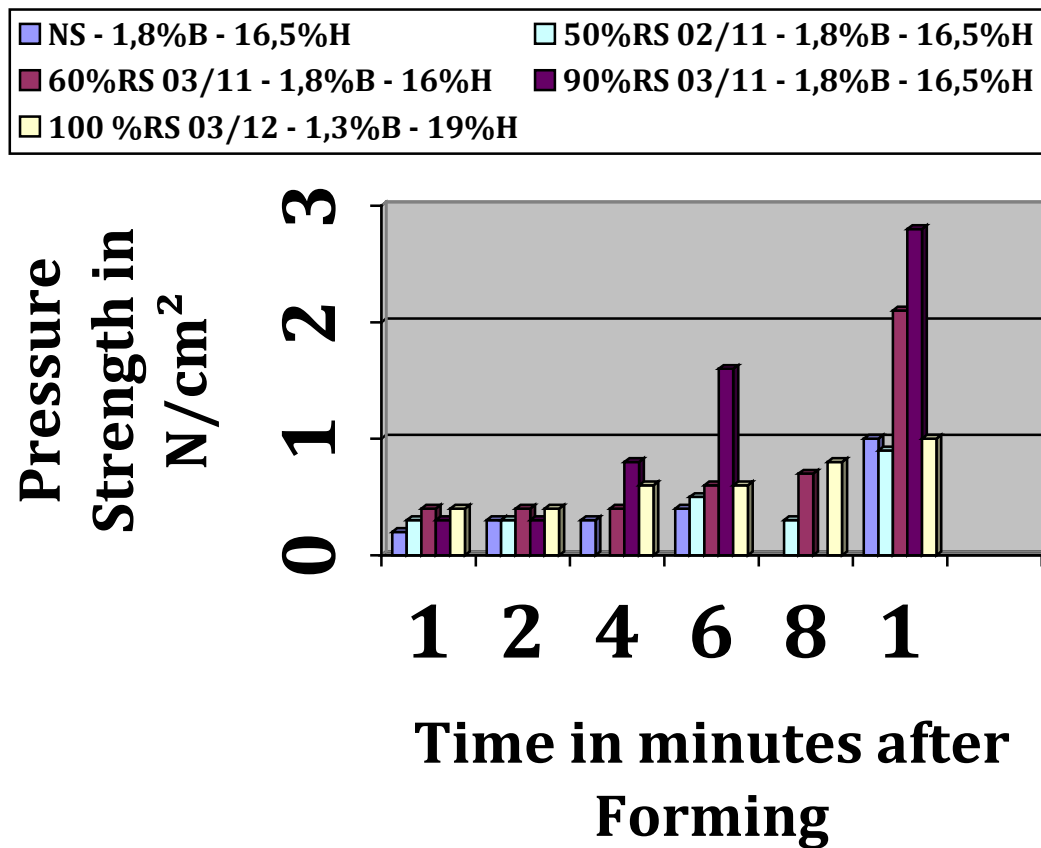

Fig.4: Detailed Pressure Strength from Fig. 3 tested with the “PFP” from DISA.

The pressure Strength graphs shows the reactivity of the sand and is influenced by residuals remaining in the sand.

It is considered as a good practical check to determine bench life of the sand. From experienced datas we know that the pressure strength should not be far above 1,0 N/cm². If the sand is manipulated above this value of 1,0 the binder bridges are affected and the end strength is depressed.

Other significant values for assessment of the reclaimed sand are the Electrical Conductivity (recommended limit < 800 µS) and Sodium content (recommended in literature < 0,20%).

Measured values for electrical conductivity are below 500 µS and for the sodium from 0,05 % to around 0,3 %.

All values shown, measurements and sampling were done out during normal production routine at AGVS.
